The Struggle with Time. 2nd edition 2006 psychiatric diseases have a highly complex etiology aggregating in families but not segregating in a traditional mendelian manner recent approaches to understanding the causes of psychiatric disease have focused on describing the genetic contribution to major psychiatric illnesses the use of large scale genome wide association studies gwas and exome sequencing has enabled a systematic exploration of genetic risk factors and identified over 100 independent genomic loci significantly associated with psychiatric diseases however there remains uncertainty about the causal genes involved in disease pathogenesis and how their function is regulated since many gwas variants reside in non coding regions the disease associated common variants might be enriched in regulatory domains including enhancers and regions of active chromatin state these lead us to focus on the possible role of non sequence based genomic variation in health and disease of particular interest are epigenetic modifications that regulate gene expression through modifications to dna rna histone proteins and chromatin the availability of high throughput profiling methods for quantifying epigenomic modifications in large numbers of samples has enabled us to perform epigenome wide association studies ewas aimed at screening methylomic variations associated with environmental exposure and disease thus systematic integration of genetic epigenetic and epidemiological approaches will contribute to improving our understanding of the molecular mechanisms underlying disease phenotypes
